City of Scottsdale
2020 Congestion Report

Introduction

This document provides traffic congestion evaluations for the City of Scottsdale. Prior versions of this *Congestion Report* were referenced as a *Levels of Service Report*; none have been published in over a decade. This report includes operational measures of individual intersections as well as measures for street corridors. The operational measures are produced through traffic modeling software based on the city's roadway network, representations of traffic signal functions, and regularly collected traffic counts. The resulting delays and other measures are presented in a tabulated format for comparison and future use. This document serves to present the current status of the City of Scottsdale's traffic operations and may function as a screening tool to identify intersections and roadway segments for more detailed evaluation.

Congestion or delay is related to the capacity of the intersection or segment and the number of users using the facility. Traditional Traffic Engineering practice assigns service ratings, termed Level of Service ("LOS"), represented by the letter grades A through F. LOS for vehicular traffic is meant to be representative of ease of use for road users to maneuver, change lanes, maintain speed, etc. LOS service ratings are based on performance measures such as delay, density or serviceability; LOS A represents the best operating conditions and LOS F being poor conditions or over capacity. It is generally preferred to have better LOS for a number of reasons including but not limited to reduced driver anxiety, reduced vehicular consumption and emissions, and time and economic losses.

LOS can be applied to various aspects of transportation including, but not limited to, intersection vehicular operation, segment/highway operation, transit service, pedestrian sidewalk congestion and bicycle operation. Some of these service rating types are useful to the City of Scottsdale while some have less meaning for Scottsdale's transportation characteristics. For example, highways are operated by the Arizona Department of Transportation, Valley Metro operates bus services and pedestrian levels of service are more relatable to cities that have a much higher proportion of pedestrian travel. This report presents intersection LOS as did prior LOS reports.

The City of Scottsdale's arterial roadway network features a grid-like infrastructure with many signalized intersections. Congestion on roads within the city is predominantly influenced by intersections. Intersection vehicular LOS's service measure is based on control delay which is the incurred delay due to conflicting traffic and the traffic control device, such as a traffic signal or a stop sign. Control delay averaged for all vehicles entering the intersection allows an overall LOS for signalized, all-way stop, and roundabout intersections. Intersection LOS rating thresholds are displayed Table 1.

Table 1: Intersection Vehicular Level of Service Thresholds

LOS	Control Delay per Vehicle	
	Signalized Intersection	Unsignalized Intersection
A	<10 seconds	<10 seconds
B	10-20 seconds	10-15 seconds
C	20-35 seconds	15-25 seconds
D	35-55 seconds	25-35 seconds
E	55-80 seconds	35-50 seconds
F	>80 seconds	>50 seconds

As seen in Table 1, LOS ratings differ by type of traffic control, reflecting that it is acceptable for signalized intersections to have longer delays than unsignalized intersections. The City of Scottsdale, like many other jurisdictions, prefers that intersections operate at LOS D or better during the peak hours. The location and character of the intersection may affect what is considered an acceptable LOS. As an example, a driver may have more patience or expect more delay at a stop sign within an urban area at a major street than at a minor street in a suburban area. The difference in expectation demonstrates acceptance of more delay in some circumstances. The City of Scottsdale does not have separate

requirements based on regional character; however, LOS issues are comparatively rare in rural areas compared to urban areas and other concerns over zoning and/or density often occurs before overall LOS reaches critical levels in rural areas.

Intersection LOS ratings are typically evaluated during weekday AM and PM peak hours – associated with peak commuter traffic. Peak hour conditions are often used for analysis when describing current conditions or projecting future conditions. Some circumstances consider other peak hours, such as weekday midday, Saturday midday, Sunday midday and evening peak hours in downtown districts. This report focuses on conditions during the weekday morning, midday and afternoon peak hours, which will be referred to as the AM peak hour, Midday/MD peak hour and PM peak hour, respectively.

While tracking individual delay for every vehicle in all intersection approach lanes at a single intersection is possible, it is not common, and traffic modeling is frequently utilized in efforts to report citywide conditions. The *Highway Capacity Manual* ("HCM", published by the Transportation Research Board), summarizes empirical data and research into mathematical equations to estimate LOS. The equations include many adjustment factors to assign a theoretical capacity and projects average delay related to counted vehicles and the estimated capacity. The City of Scottsdale currently utilizes the computer software program Synchro analyze LOS at the city's intersections. Synchro utilizes equations and adjustments as defined in the HCM, as well as its proprietary algorithms that are able to evaluate prevalent conditions in Scottsdale that cannot be evaluated with HCM procedure. Scottsdale's Synchro models are maintained to represent typical traffic conditions for use in maintenance and future planning of Scottsdale streets. Algorithms and models are not expected to provide perfect estimates of actual traffic conditions; traffic in general also has inherent variance by minute, hour, weekday and season.

Figures 1 through 3 present an overall summary of all evaluated intersections during the analyzed peak hours. The figures show the LOS distribution and a plot of LOS with respect to the average number of stops the average entering vehicle experiences by intersection. The vast majority of evaluated intersections operate at LOS D or better. Average stops per vehicle varied by intersection and peak hour from less than 0.1 up to 0.91. Stops per vehicle and vehicular delay, which is related to LOS, are both desired to be minimized at intersections as much as reasonably possible to reduce aforementioned societal costs. Outputs for individual intersections are tabulated in the *Intersection Levels of Service* sections of this report. An acceptable LOS at an intersection is not necessarily an indication that mitigation measures improvements aren't needed. Likewise, poor LOS isn't necessarily an indication that mitigation measures will provide a benefit due to progression, saturation, and other potential limitations. City Transportation staff may review specific intersections for more detailed evaluation and real time observations to determine if any signal parameters need adjustment or for consideration of a capital improvement project. Additional charts with enhanced details are presented in the next section of the report. Note: The Synchro models and data are maintained and provided by Traffic Management Center. The data were collected at different times between 2016 and 2019. The results in this report do not reflect current traffic conditions. Analyses are based on collected data prior to traffic effects due to Covid-19 response; traffic conditions have and continue to vary; this document is intended to present long term typical conditions.

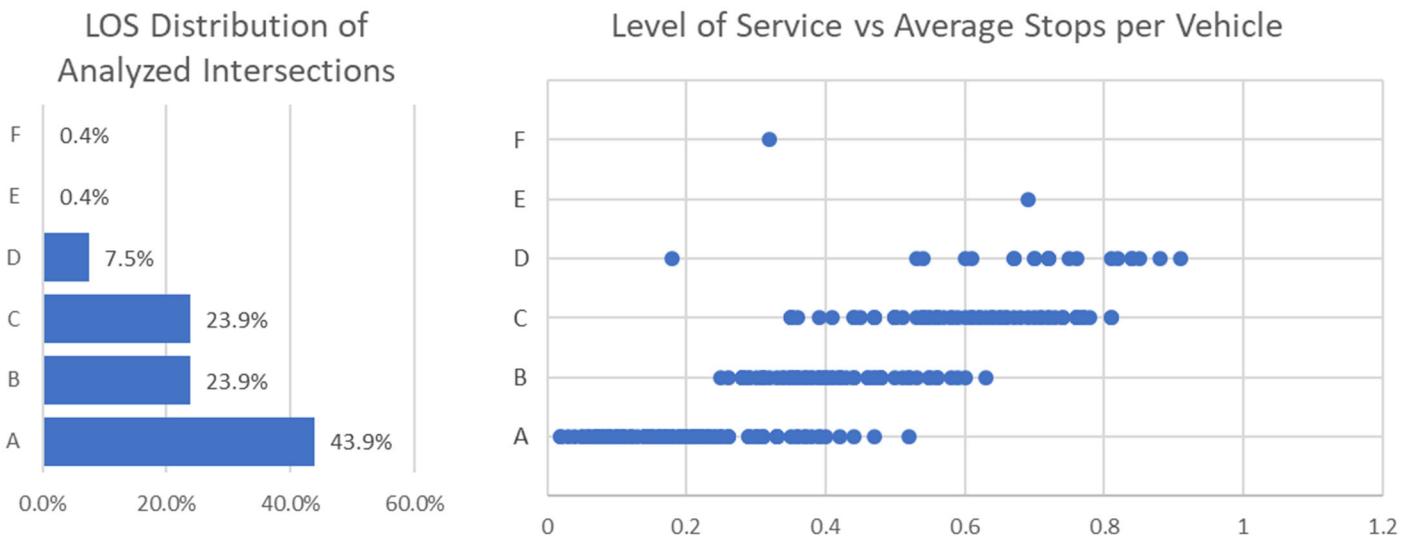

Figure 1: AM Peak Hour LOS Distribution and LOS versus Average Stops per Vehicle

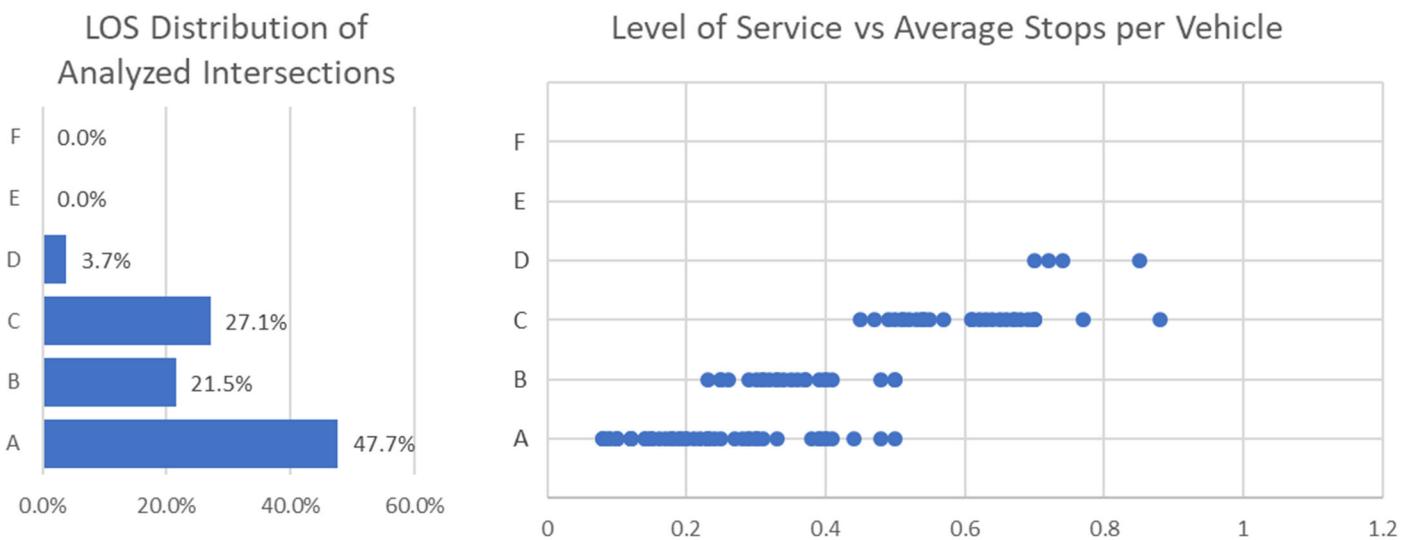

Figure 2: Midday Peak Hour LOS Distribution and LOS versus Average Stops per Vehicle

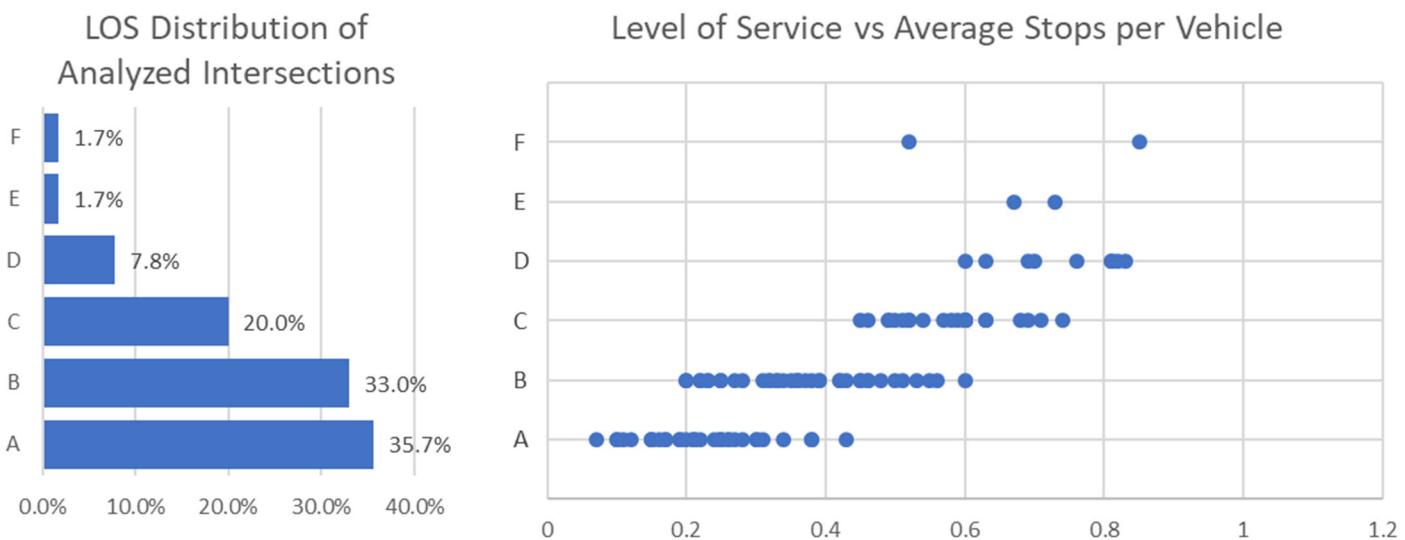

Figure 3: PM Peak Hour LOS Distribution and LOS versus Average Stops per Vehicle

Efforts to optimize individual intersection operations is layered with improving continuous travel along large corridor sections. Optimization of interconnected traffic signal controllers can improve signal progression where a series of signalized intersections are better coordinated to allow vehicles to travel further before being stopped at a traffic signal and reduce instances of vehicle arrival during a red phase. This effort is often referred to as ‘signal progression’ which aims to reduce overall delay through several coordinated intersections rather than preset or uncoordinated, individual intersections. The service measure often used for how well a corridor operates is the average travel speed and its comparison with the posted travel speed. Synchro’s corridor analysis uses intersection operational parameters to predict corridor delays at intersections which are used to estimate average travel speed. The evaluated travel speed is directly related to the speed limit(s) of the roadway and delays experienced at intersections according to the modeling software.

The box and whisker chart in Figure 4 depict the percent of posted speed, that is, the average travel speed divided by average posted speed limit, per corridor and direction for the AM, midday and PM peak hours. A similar but more detailed chart with enhanced details is presented in the next section of the report.

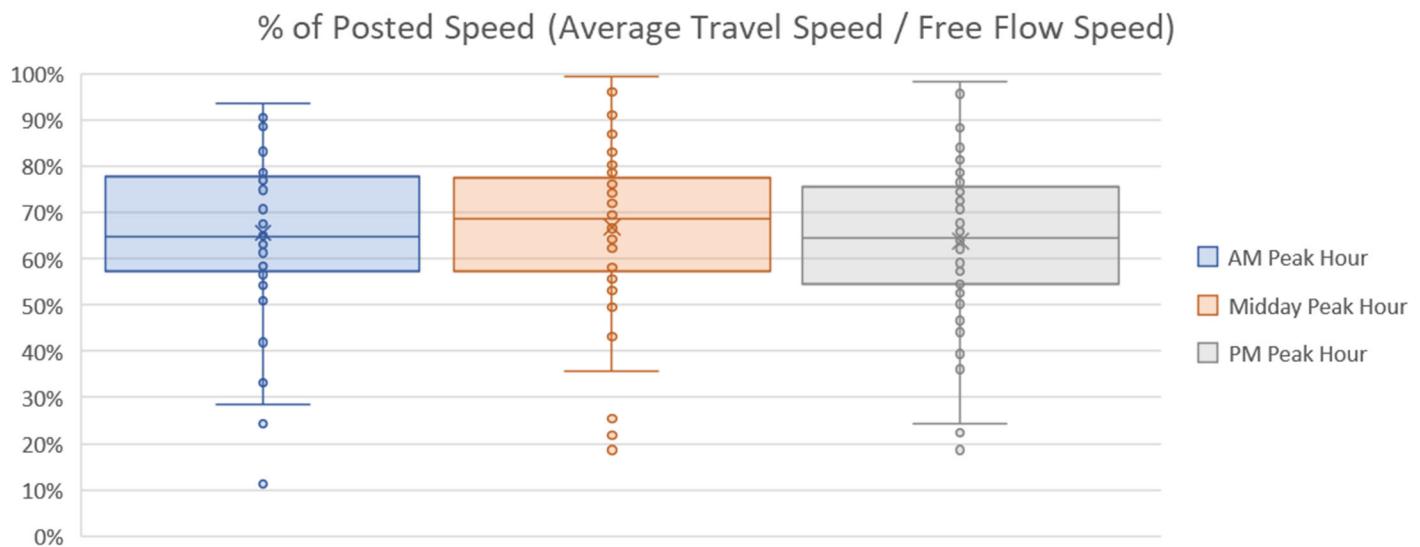

Figure 4: Travel Speed to Posted Speed Percentage per Corridor by Peak Hour

The speeds for the evaluated corridors average 65 percent of the free flow speed during the AM peak hour, 69 percent during the midday peak hour and 64 percent during the PM peak hour. Due to modeling limitations, some corridors that were evaluated to have low-outlying average travel speeds may be less accurate. This can be exaggerated for a shorter corridor that contains a major intersection with heavy delays. Transportation staff can review specific corridors in more detail using real time observations to determine if any improvements may be possible without impacting other corridors. Transportation staff regularly reviews intersection timing for improving traffic flow and overall progression. Individual adjustments are unlikely to have a drastic positive effect on analysis results published herein. As Scottsdale continues to increase in population and employment and additional traffic signals are constructed, average speeds may decrease over time. Outputs for individual corridors are tabulated in the *Corridor Data* sections of this report.

**City of Scottsdale
2020 Congestion Report**

Intersection LOS, Overall - Sorted Alphabetically

NOTES:

Digits are listed before letters; for example, 100th Street is listed before Alma School Road. Numbered streets names are treated as a name, not a value; for example, 100th Street is listed before 90th Street. Roadways with two street names are alphabetized by the first street name ignore the second listed street name; for example, 64th Street/Glavin Parkway & McDowell Road is listed before 64th Street & Oak Street.

Intersections have a displayed rank by analysis period. Rank is determined by level of service ("LOS"), worst to best, then by average delay per vehicle.

City of Scottsdale
2020 Congestion Report

Intersection LOS - AM Peak Hour, Sorted by LOS Category

NOTE:

Intersections have a displayed rank by analysis period. Rank is determined by level of service ("LOS"), worst to best, then by average delay per vehicle.

2020 Congestion Report**

Intersection LOS - Midday Peak Hour, Sorted by LOS Category

NOTE:

Intersections have a displayed rank by analysis period. Rank is determined by level of service ("LOS"), worst to best, then by average delay per vehicle.

N/S_STREET	E/W_STREET	Rank	Midday Peak Hour				AM Peak		PM Peak

***Intersection LOS - AM Peak Hour, Sorted by LOS Category
- Arterial & Arterial Intersections Only***

NOTES:

Intersections in this section include only those whose intersecting streets are each classified as an arterial at least one of the approach legs. Couplets, specifically Goldwater Boulevard and Drinkwater Boulevard, are grouped with arterial classifications.

Intersections have a displayed rank by analysis period. Rank is determined by level of service ("LOS"), worst to best, then by average delay per vehicle.

City of Scottsdale
2020 Congestion Report

***Intersection LOS - Midday Peak Hour, Sorted by LOS Category
- Arterial & Arterial Intersections Only***

NOTES:

Intersections in this section include only those whose intersecting streets are each classified as an arterial at least one of the approach legs. Couplets, specifically Goldwater Boulevard and Drinkwater Boulevard, are grouped with arterial classifications.

Intersections have a displayed rank by analysis period. Rank is determined by level of service ("LOS"), worst to best, then by average delay per vehicle.

2020 Congestion Report

***Intersection LOS - Midday Peak Hour, Sorted by LOS Category
- Arterial & Arterial Intersections Excluded***

NOTES:

Intersections in this section include only those whose intersecting streets are not both classified as an arterial at least one of the approach legs. Couplets, specifically Goldwater Boulevard and Drinkwater Boulevard, are grouped with arterial classifications.

Intersections have a displayed rank by analysis period. Rank is determined by level of service ("LOS"), worst to best, then by average delay per vehicle.

Corridor Data - Overall

NOTES:

Segments have a displayed rank by analysis period by the percent of posted speed. Percent of posted speed is calculated by dividing the length of the corridor by the sum of the estimated signal delay and corridor's theoretical travel duration - excluding delays - at the posted speed limit.

Corridor Data - PM Peak Hour, Sorted by Percent of Posted Speed

NOTES:

Segments have a displayed rank by analysis period by the percent of posted speed. Percent of posted speed is calculated by dividing the length of the corridor by the sum of the estimated signal delay and corridor's theoretical travel duration - excluding delays - at the posted speed limit.
